Kohn-Sham Density Functional Theory

$$H[\rho]\psi_i(x) = \left(-\frac{1}{2}\Delta + V_{\text{ion}} + \int dx' \frac{\rho(x')}{|x-x'|} + V_{\text{xc}}[\rho] \right) \psi_i(x) = \epsilon_i \psi_i(x),$$
$$\rho(x) = 2 \sum_{i=1}^{N/2} |\psi_i(x)|^2, \quad \int \psi_i \psi_j = \delta_{ij}.$$

- ▶ Single particle formalism with in principle exact accuracy.
- ▶ N is the number of electrons (2 comes from spin). V_{ion} is the ionic potential. V_{xc} is the exchange-correlation potential.
- ▶ Nonlinear eigenvalue problem.

Standard flowchart

Self-consistent field iteration:

- ▶ Diagonalization: Lowest $N/2$ eigenvalues ε_i and eigenfunctions ψ_i , $\rho_{\text{out}}(x) = 2 \sum_{i=1}^{N/2} |\psi_i(x)|^2$.
- ▶ Most time consuming step.
- ▶ Focus of this talk: $H[\rho_{\text{in}}] \rightarrow \rho_{\text{out}}$.

Computational cost of KSDFT

Typical cubic computational scaling:

Size	Time
10	1 sec
100	17 min
1000	11.6 day

$\mathcal{O}(nN^3)$ cost:

- ▶ **diagonalization cost:** N^3 .
- ▶ **discretization cost:** the number of basis functions per atom (n), n is typically 500 ~ 5000.

Importance of discretization cost

- ▶ **Diagonalization:** $\mathcal{O}(nN^3)$ for all systems.
- ▶ **Selected inversion:** $\mathcal{O}(N)$ for quasi-1D system, $\mathcal{O}(N^{1.5})$ for quasi-2D system, and $\mathcal{O}(N^2)$ for 3D bulk system.

$$\rho = \text{diag} \frac{2}{1 + e^{\beta(H-\mu)}} \approx \text{diag} \sum_{i=1}^P \frac{\omega_i}{z_i I - H}$$

Importance of discretization cost

- ▶ **Diagonalization:** $\mathcal{O}(nN^3)$ for all systems.
- ▶ **Selected inversion:** $\mathcal{O}(n^3N)$ for quasi-1D system, $\mathcal{O}(n^3N^{1.5})$ for quasi-2D system, and $\mathcal{O}(n^3N^2)$ for 3D bulk system.

$$\rho = \text{diag} \frac{2}{1 + e^{\beta(H-\mu)}} \approx \text{diag} \sum_{i=1}^P \frac{\omega_i}{z_i I - H}$$

1000	1000	9,772	1,000,000

- ▶ **Goal today:** Reduce the number of basis functions per atom.

Outline

Introduction

Building physics into basis sets

Discontinuous Galerkin Framework

Constructing adaptive local basis function

Numerical examples

Future work and conclusion

Building atomic physics into basis functions I

- ▶ Rapid but “inert” oscillation near the nucleus.
- ▶ Smooth oscillation in the interstitial bonding region.

Building atomic physics into basis functions II

Atomic orbital as basis functions:

- ▶ Gaussian type orbitals (GTO)
- ▶ Numerical atomic orbital (NAO) [Blum et al. 2009]

Mixed (enriched) basis functions:

- ▶ Augmented plane-wave (APW) [Slater, 1937]
- ▶ Linear augmented-plane-wave (LAPW) [Andersen, 1975]
- ▶ Projector augmented-wave (PAW) [Blöchl, 1994]
- ▶ Enriched finite element [Sukumar and Pask, 2009]

Difficulty of atomic orbitals

Lack of environmental effect

Difficulty of atomic orbitals

Lack of environmental effect

Atomic orbital as basis functions:

- ▶ Fine tuning of the parameters for different chemical elements, exchange-correlation functional and even different environment.
- ▶ Overcomplete and incomplete basis sets.

Difficulty of atomic orbitals

Lack of environmental effect

Atomic orbital as basis functions:

- ▶ Fine tuning of the parameters for different chemical elements, exchange-correlation functional and even different environment.
- ▶ Overcomplete and incomplete basis sets.

Mixed (enriched) basis functions:

- ▶ Fine tuning.
- ▶ Relatively large number of basis functions per atom.

Building environmental effect into basis functions

Construct the **local** basis functions **on the fly** by **solving a small part of the system**.

Questions:

- ▶ How to obtain basis function?
- ▶ How to patch basis functions together?

Our answer:

- ▶ **Local solve** to obtain **discontinuous** basis function.
- ▶ **Discontinuous Galerkin** framework to patch basis functions together.

Outline

Introduction

Building physics into basis sets

Discontinuous Galerkin Framework

Constructing adaptive local basis function

Numerical examples

Future work and conclusion

Introduction

Discontinuous Galerkin:

- ▶ Finite element method with discontinuous basis functions.
- ▶ Penalty on the inter-element jump to enforce inter-element continuity.

Introduction

Discontinuous Galerkin:

- ▶ Finite element method with discontinuous basis functions.
- ▶ Penalty on the inter-element jump to enforce inter-element continuity.

APW, LAPW etc. [already discontinuous](#).

History more than four decades

Early work on using penalty to impose boundary condition:

- ▶ [Lions, 1968], [Aubin, 1970],[Babuška, 1973], [Nitsche, 1971]

Interior penalty for elliptic and parabolic problems:

- ▶ [Babuška and Zlámal, 1973] Penalty to impose C^1 continuity for fourth-order problem.
- ▶ [Douglas and Dupont, 1976]: elliptic and parabolic.
- ▶ [Arnold, 1982] interior penalty formulation.
- ▶ [Arnold, Brezzi, Cockburn et al 2002] unified analysis.

Hyperbolic equation:

- ▶ [Cockburn and Shu, 1991], [Cockburn and Shu, 1998] Runge-Kutta DG.
- ▶ [Cockburn, Karniadakis and Shu, 2000]: Review

Setup

Let \mathcal{T} be a collection of uniform rectangular partitions of Ω

$$\mathcal{T} = \{E_1, E_2, \dots, E_M\},$$

and \mathcal{S} be the collection of surfaces corresponds to \mathcal{T} .

Inner products

$$\langle \mathbf{v}, \mathbf{w} \rangle_E = \int_E \mathbf{v}^*(x) \mathbf{w}(x) dx,$$

$$\langle \mathbf{v}, \mathbf{w} \rangle_S = \int_S \mathbf{v}^*(x) \cdot \mathbf{w}(x) ds(x),$$

$$\langle \mathbf{v}, \mathbf{w} \rangle_{\mathcal{T}} = \sum_{i=1}^M \langle \mathbf{v}, \mathbf{w} \rangle_{E_i},$$

$$\langle \mathbf{v}, \mathbf{w} \rangle_{\mathcal{S}} = \sum_{S \in \mathcal{S}} \langle \mathbf{v}, \mathbf{w} \rangle_S.$$

Kohn-Sham energy functional

The variational problem

$$E_{\text{eff}}(\{\psi_i\}) = \frac{1}{2} \sum_{i=1}^N \int |\nabla \psi_i(\mathbf{x})|^2 d\mathbf{x} + \int V_{\text{eff}}(\mathbf{x}) \rho(\mathbf{x}) d\mathbf{x} + \sum_{\ell} \gamma_{\ell} \sum_{i=1}^N |\langle \mathbf{b}_{\ell}, \psi_i \rangle|$$

with orthonormality constraints $\langle \psi_i, \psi_j \rangle = \delta_{ij}$. The effective one-body potential V_{eff}

$$V_{\text{eff}}[\rho](\mathbf{x}) = V_{\text{ext}}(\mathbf{x}) + \int \frac{\rho(\mathbf{y})}{|\mathbf{x} - \mathbf{y}|} d\mathbf{y} + \epsilon'_{\text{xc}}[\rho(\mathbf{x})].$$

DG energy functional: interior penalty formulation

$$E_{\text{DG}}(\{\psi_i\}) = \frac{1}{2} \sum_{i=1}^N \langle \nabla \psi_i, \nabla \psi_i \rangle_{\mathcal{T}} + \langle \mathbf{V}_{\text{eff}}, \rho \rangle_{\mathcal{T}} + \sum_{\ell} \gamma_{\ell} \sum_{i=1}^N |\langle \mathbf{b}_{\ell}, \psi_i \rangle_{\mathcal{T}}|^2 \\ - \sum_{i=1}^N \langle \{\{\nabla \psi_i\}\}, [[\psi_i]] \rangle_S + \frac{\alpha}{h} \sum_{i=1}^N \langle [[\psi_i]], [[\psi_i]] \rangle_S.$$

$\{\{ \cdot \}\}$ and $[[\cdot]]$ are **average and jump operators** across surfaces.

$$\{\{q\}\} = \frac{1}{2}(q_1 + q_2) \quad \text{on } S.$$

$$[[u]] = u_1 n_1 + u_2 n_2 \quad \text{on } S.$$

- ▶ S : shared by elements K_1 and K_2 .
- ▶ n_1 and n_2 as unit normal vectors on S pointing exterior to K_1 and K_2 .

Galerkin I

For each element E_k choose a set of basis functions $\{\varphi_{k,j}\}_{j=1}^{J_k}$, and extend $\varphi_{k,j}$ to the whole computational domain Ω by setting it to be 0 on the complement of E_k .

$$\mathcal{V} = \text{span}\{\varphi_{k,j}, E_k \in \mathcal{T}, j = 1, \dots, J_k\}.$$

Minimize for $\{\psi_i\} \subset \mathcal{V}$ in the approximation space \mathcal{V} leads to the eigenvalue problem for any $\mathbf{v} \in \mathcal{V}$

$$\begin{aligned} \frac{1}{2} \langle \nabla \mathbf{v}, \nabla \psi_i \rangle_{\mathcal{T}} - \frac{1}{2} \langle [[\mathbf{v}]], \{ \{ \nabla \psi_i \} \} \rangle_{\mathcal{S}} - \frac{1}{2} \langle \{ \{ \nabla \mathbf{v} \} \}, [[\psi_i]] \rangle_{\mathcal{S}} + \\ \frac{\alpha}{h} \langle [[\mathbf{v}]], [[\psi_i]] \rangle_{\mathcal{S}} + \langle \mathbf{v}, \mathbf{V}_{\text{eff}} \psi_i \rangle_{\mathcal{T}} + \sum_{\ell} \gamma_{\ell} \langle \mathbf{v}, \mathbf{b}_{\ell} \rangle_{\mathcal{T}} \langle \mathbf{b}_{\ell}, \psi_i \rangle_{\mathcal{T}} \\ = \lambda_i \langle \mathbf{v}, \psi_i \rangle_{\mathcal{T}}. \end{aligned}$$

Galerkin II

Setting $v = \varphi_{k',j'}$ and denoting

$$\psi_i = \sum_{k \in \mathcal{T}} \sum_{j=1}^{J_k} \mathbf{c}_{i;k,j} \varphi_{k,j},$$

gives the following linear system

$$\begin{aligned} & \sum_{k,j} \left(\frac{1}{2} \langle \nabla \varphi_{k',j'}, \nabla \varphi_{k,j} \rangle_{\mathcal{T}} - \frac{1}{2} \langle [[\varphi_{k',j'}]], \{ \{ \nabla \varphi_{k,j} \} \} \rangle_{\mathcal{S}} \right. \\ & - \frac{1}{2} \langle \{ \{ \nabla \varphi_{k',j'} \} \}, [[\varphi_{k,j}]] \rangle_{\mathcal{S}} + \frac{\alpha}{h} \langle [[\varphi_{k',j'}]], [[\varphi_{k,j}]] \rangle_{\mathcal{S}} + \langle \varphi_{k',j'}, \mathbf{V}_{\text{eff}} \varphi_{k,j} \rangle_{\mathcal{T}} \\ & \left. + \sum_{\ell} \gamma_{\ell} \langle \varphi_{k',j'}, \mathbf{b}_{\ell} \rangle_{\mathcal{T}} \langle \mathbf{b}_{\ell}, \varphi_{k,j} \rangle_{\mathcal{T}} \right) \mathbf{c}_{i;k,j} = \lambda_i \sum_{k,j} \langle \varphi_{k',j'}, \varphi_{k,j} \rangle \mathbf{c}_{i;k,j}. \end{aligned}$$

Eigenvalue problem

$$Ac_i = \lambda_j Bc_i.$$

We can actually choose $B = I$. Then we have standard eigenvalue problem

$$Ac_i = \lambda_j c_i.$$

The electron density is given by

$$\tilde{\rho} = \sum_{i=1}^N \sum_k \left(\sum_{j=1}^{J_k} c_{i;k,j} \varphi_{k,j} \right)^2.$$

Outline

Introduction

Building physics into basis sets

Discontinuous Galerkin Framework

Constructing adaptive local basis function

Numerical examples

Future work and conclusion

Setup of local problem

- ▶ Buffer region associated with E_k : $Q_k \supset E_k$.
- ▶ Restrict the effective Hamiltonian on Q_k by assuming the periodic boundary condition on ∂Q_k and obtain H_{eff, Q_k} .
- ▶ Take the first several eigenfunctions of H_{eff, Q_k} called $\{\varphi_{k,j}\}$, $j = 1, \dots, J_k$ and restrict them on E_k .

Red: E_k ;

Red+Blue: Q_k

Standard eigenvalue problem

Recall that

$$Ac_i = \lambda_i Bc_i, \quad B = \begin{pmatrix} B_1 & & \\ & \ddots & \\ & & B_M \end{pmatrix}, \quad \{B_k\}_{jj'} = \langle \varphi_{k',j'}, \varphi_{k,j} \rangle.$$

SVD filtering to obtain an **orthonormal basis set** and to avoid numerical degeneracy:

1. For each k , form matrix $M_k = (\varphi_{k,1}, \varphi_{k,2}, \dots, \varphi_{k,J_k})$;
2. Calculate SVD decomposition $UDV^* = M_k$;
3. For a threshold δ , find \tilde{J}_k such that $|\lambda_{k,\tilde{J}_k}| > \delta$ and $|\lambda_{k,\tilde{J}_k+1}| < \delta$. Take $\tilde{\varphi}_{k,j}$ be the j -th column of U .
4. Set $J_k \leftarrow \tilde{J}_k$ and $\varphi_{k,j} \leftarrow \tilde{\varphi}_{k,j}$ for $j = 1, \dots, \tilde{J}_k$.

Overall algorithm

1. Set $n = 0$, take elements partition \mathcal{T} and an initial guess of density ρ_0 ;
2. Form the effective potential $V_{\text{eff}}[\rho_n]$ and the effective Hamiltonian $H_{\text{eff}}[\rho_n]$;
3. For each element $E_k \in \mathcal{T}$, solve the restricted Hamiltonian on buffer region Q_k , and obtain $\{\varphi_{k,j}\}, j = 1, \dots, J_k$ using SVD filtering.
4. Solve standard eigenvalue problem $A c_i = \lambda_i c_i$ to obtain $c_{i;k,j}$ and get the density $\tilde{\rho}$.
5. Mixing step: Determine ρ_{n+1} from ρ_n and $\tilde{\rho}$;
6. If $\|\rho_n - \tilde{\rho}\| \leq \delta$, stop; otherwise, go to step (2) with $n \leftarrow n + 1$.

Advantage of the current framework

- ▶ Automatic basis set reduction.
- ▶ Capture both atomic and environmental effect automatically.
- ▶ Complete basis set.
- ▶ Flexible framework due to discontinuous character: can be combined with polynomials or other existing basis functions.

Outline

Introduction

Building physics into basis sets

Discontinuous Galerkin Framework

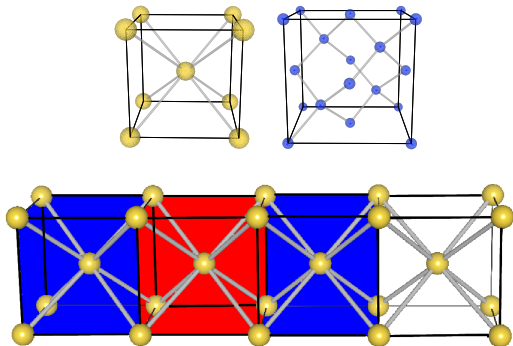

Constructing adaptive local basis function

Numerical examples

Future work and conclusion

Setup

- ▶ Target accuracy (chemical accuracy): total energy error 10^{-3} au/atom.
- ▶ LDA. Real space local and non-local pseudopotential [Shaw, 1968].
- ▶ Buffer extra size.
- ▶ Sodium (Na) and Silicon (Si).

Quasi-1D: periodic case

Left: Na with 4 unit cells. Buffer extra size 0.25 (red triangle with solid line), 0.50 (black diamond with solid line), and 0.75 (blue star with solid line). Right: Si with 4 unit cells. The legend is the same as in (a). The black dashed horizontal line refers to the target accuracy 10^{-3} au per atom.

Quasi-1D: Long supercell

Na system with increasing supercell dimension along z-direction. The buffer extra size is 0.50. 3 enrichment basis function per atom and 5 enrichment basis function per atom are represented by blue diamond with dashed line, and red triangle with solid line, respectively.

Quasi-1D: random perturbation

Disordered Na (red diamond with solid line) and Si (blue diamond with dashed line), with buffer extra size 0.50.

Quasi-2D and 3D Bulk system

Left: Quasi-2D Na system with buffer extra sizes 0.50 (red triangle with solid line), and buffer extra size 1.00 (blue triangle with dashed line). Right: Bulk 3D Na system with buffer extra sizes 0.50 (red diamond with solid line), and buffer extra size 1.00 (blue diamond with dashed line).

Computational efficiency

- ▶ Treat the matrix A as **dense** matrix.
- ▶ Parallelized implementation of buffer solve.
- ▶ Parallelized implementation of DG matrix assembly.
- ▶ Use ScaLAPACK subroutine pdsyevd as parallel eigenvalue solver.

Computational time per processor comparison:

Atom#	Proc#	Global time	DG time
128	64	35 s	4 s
432	216	248 s	35 s

Outline

Introduction

Building physics into basis sets

Discontinuous Galerkin Framework

Constructing adaptive local basis function

Numerical examples

Future work and conclusion

Future work

Methodology:

- ▶ Improvement over periodic boundary condition in the buffer.
- ▶ All electron calculation.
- ▶ Molecular dynamics.

Code development:

- ▶ Discontinuous Galerkin framework with existing atomic orbital type basis functions.
- ▶ **Combine with Fermi Operator Expansion methods:**
 $\mathcal{O}(n^3 N)$ for quasi-1D system, $\mathcal{O}(n^3 N^{1.5})$ for quasi-2D system, and $\mathcal{O}(n^3 N^2)$ for 3D bulk system.
- ▶ Pseudopotentials. GGA.

Application:

- ▶ Long molecules, nanotube and nanowire (quasi-1D)
- ▶ Large scale surface problem. (quasi-2D)

Conclusion

Adaptive:

- ▶ Tuning-free basis set reduction with small number of enrichment functions.
- ▶ Capture both atomic and environmental effect automatically.

Local:

- ▶ Discontinuous nature.
- ▶ Important for the block sparsity of the assembled DG matrix.

Flexible:

- ▶ Flexible framework due to discontinuous character.

Fast:

- ▶ Computationally more efficient due to reduced basis set.

Thanks for your attention!
